APPEAL BRIEF

Mail Stop Appeal Brief - Patents
Commissioner for Patents
P.O. Box 1450
Alexandria, VA 22313-1450

Sir:

This brief is an appeal from the Office Action mailed June 16, 2006, finally rejecting claims 1-27. A Notice of Appeal was timely filed on December 15, 2006, such that the time for filing this Appeal Brief is thereby set for July 15, 2007. Accordingly, a petition for a five month extension of time accompanies this Appeal Brief. It is submitted that the application and claims are or will shortly be properly formed and the issues are ripe for appeal.

I. REAL PARTY IN INTEREST

The real party in interest is Bird Barrier America, Inc., the assignee of the present application.

II. RELATED APPEALS AND INTERFERENCES

There are no related appeals or interferences.

III. STATUS OF CLAIMS

Pending Claims, Elected Claims, Withdrawn Claims & Claims on Appeal:

Claims 1-27 were pending and finally rejected in the June 16, 2006 Office Action. There were no restrictions or elected claims. See the next section of this Brief, however, for an explanation of the current status of post-final amendments, and the claims which will be addressed in this Appeal Brief.

IV. STATUS OF AMENDMENTS

Several proposed amendments to the claims after final have been lodged, although none has yet been entered. In an advisory action dated May 11, 2007, however, the Examiner noted that the proposed amendment filed April 27, 2007 would be entered if the total number of proposed claims in that amendment were reduced to 27. Since that time, a new Proposed Amendment after Final (filed via Express Mail deposit on July 6, 2007) has been lodged which reduces the proposed claims to a total of 27. Because of the similarity between this latest proposed Amendment after Final, and that filed on April 27, 2007 (which the Examiner indicated would be entered if the total number of claims were reduced to 27), it is anticipated by applicant that the July 6, 2007 Proposed Amendment after Final will be entered by the Examiner. Accordingly, this brief will address those claims and the prior art addressed therein, as it is believed that the prior made of record since the June 16, 2006 Office Action is more pertinent than that of record at that time. Accordingly, as noted in the

attached Claims Appendix, applicant believes that the claims that will be at issue in this Appeal are those set forth in the July 6, 2007 Proposed Amendment; that is, claims 1, 2, 3, 5, 9, 10, 11, 12, 13, 14, 15, 16, 18, 19, 20, 21, 23, 26, 27, 28, 29, 30, 31, 32, 33, 34, and 35.

V. SUMMARY OF CLAIMED SUBJECT MATTER

The claimed invention is a pest deterrent device that includes at least two braided conductive element that are sewn to a non-conductive, flexible, extruded base such that when the base is bent in either convex or concave fashion, at least a portion of the stress that such flex places on the braided conductive elements is absorbed by the individual strands in the conductive elements expanding apart from, or contracting towards, one another. (See *e.g.*, Figs. 1, 6, 7, 8 and 9; Appl. ¶¶ 010, 011, 012, 024, et seq).

This type device, which will find primary utility as a bird deterrent device, fulfills a long felt need for an effective electric deterrent that can be attached to other than flat surfaces, and when attached can more effectively withstand the rigors of the weather, differing coefficients of expansion between the base and the conductive element, and other hazards, such as being stepped on or crushed by, for example, window washers and their equipment.

As a review of the prior art will show, creating such a flat, flexible, effective deterrent device that will allow it to be attached to radically curved surfaces without breaking down, that will stand up to constant exposure to the elements, and periodic but repeated abuse by window washers, that keeps the conductive elements in place, and at the same time, keeps the conductive elements properly exposed to the bird or pest to be deterred such that incidental contact will be with both elements thus generating the electric shock, has proven elusive.

The evidence in the record will also show, in addition to long felt need and attempts by other, slavish copying, all of which present compelling secondary considerations of the non-obviousness of the claimed invention.

VI. GROUNDS OF REJECTION TO BE REVIEWED ON APPEAL

In the Final Office Action dated June 16, 2006, then pending Claims 1-27 were rejected under 35 U.S.C. §103(a) over Spooner, USPat.App.Pub.No. 2002/0092481. Since the Final Office Action, an attorney for the company that has marketed a copy of the claimed invention has made six (6) submissions of prior art under 35 USC § 301. During interviews with the Examiner to discuss the prior art submitted, applicant has come to believe that the Examiner considers one such prior art reference, Bailey (WO1984004022A1), to be the most relevant prior art of record, and more relevant than Spooner. Accordingly, to the extent that the pending Proposed Amendment After Final does not result in a Notice of Allowance of all claims, applicant anticipates that the ground for rejection will be under 35 U.S.C. §103(a) over Bailey.

Accordingly, this Appeal Brief will address pending claims 1, 2, 3, 5, 9, 10, 11, 12, 13, 14, 15, 16, 18, 19, 20, 21, 23, 26, 27, 28, 29, 30, 31, 32, 33, 34, and 35 as having been rejected under 35 U.S.C. §103(a) over Bailey. Applicant reserves the right to file an amended brief in the event the pending Proposed Amendment After Final is not entered, or there are other grounds for rejection of any claims.

VII. ARGUMENT

A. Bailey Does Not Teach or Suggest the Invention as Claimed

The disclosure by Bailey relates generally to an electric device for deterring birds that might land on “the deck, roof or **other flat surface** and immediately walk to the gunwale for a view of the water.” (Page 1, lines 32-33, emphasis added). Bailey later reiterates that his focus is on protecting a

“broad” and “horizontal” surface. (Id. Page 2, lines 4-5, and page 3, lines 10-16 and 23-24). In other words, Bailey’s focus was directed primarily to such surfaces, and there was no need for him to consider, and he did not consider, discuss or disclose, the design requisites for a device that could be attached to a radically curved surface in addition to a relatively flat, horizontal (and typically, broad) surface.

Bailey then discloses three embodiments for use on these relatively flat surfaces: Firstly, if the boat deck is constructed of timber or fiberglass (that is, a non-conductive material), then the “conduction means are flat metal ribbons which are laid in parallel pairs closely-spaced along the surface of the boat . . .” and attached directly to it by adhesive tape. (Page 2, lines 14-20).¹ Secondly, if the boat is constructed of metal, then “a single conductor can be laid over the boat insulated therefrom by a thin ribbon insulator.”² (Page 2, lines 21-23). Thirdly, instead of attaching the conductive element(s) directly to the boat surface, “it may be instead affixed upon a plastics sheeting which can be laid out and recovered [from the boat deck] as desired.” (Page 5, lines 5-7).

Thus, there is no discussion of, or teaching with respect to, creating a **flexible** deterrent device that is designed for attachment not only to flat surfaces, but also to **curved** surfaces as well. As the prior art of record shows, there are any number of electric deterrent devices that have been designed to be attached to relatively flat surfaces, and very few that have tried to create an effective

¹ In this embodiment, there is no need for an insulation because the boat surface itself is insulating. Bailey also discloses laying the closely-spaced pairs “upon a common insulating layer” (page 4, lines 36-37). This is a bit confusing, since Bailey uses the “closely-spaced pairs” only with the timber or fiberglass boat that doesn’t require an insulating layer. The most reasonable interpretation of this statement seems to be that by “common insulating layer” Bailey was referring to the “plastics sheeting” in the third embodiment discussed *infra*.

² In this instance, the metal boat surface as the “ground” so only a single “hot” conductive element is used.

electric deterrent device for attachment to both flat and radically curved surfaces. And Bailey is of the former, not the latter. In fact, the words “flexible” or “curve” or “curved” don’t even appear anywhere in the Bailey disclosure.³ Not once. Not surprisingly, nor is there any reference or teaching within Bailey as to how his device would be attached to a curved surface.

Also, Bailey provides scant disclosure or teaching as to the “insulating layer” and nothing that teaches or suggests the **extruded** elongate flexible base of the current device. The only descriptive references in Bailey to the insulating layer is that it is a “thin ribbon insulator” (page 2, line 24), or a “thin insulating layer” (page 3, line 25), a “thin underside electrically insulating layer” (page 4, lines 29-30), or a “plastics sheeting” (page 5, line 9).⁴

Therefore, Applicant respectfully suggests that Bailey lacks the important “flexible base” element of the pending claims.

Very significantly on this point, **even the attorney for Bird B Gone, the company that has copied this invention, who has made six submissions of prior art in this prosecution, concedes as much** (see claim chart on page 1 of the 4th Fish Submission⁵ wherein there is no reference to any

³ Bailey describes the surfaces for possible application of his device as being “moored boats, the coping and cornices of buildings, railings and the like” (page 1, lines 5-6), the “upper portion of the rail” (page 1, line 37), the “topside of rigging” (page 3, line 33) and the “topside of a metal rail” (page 3, line 35) – all relatively straight, flat surfaces. The embodiments shown and described, however, are all attached to a boat deck surface.

⁴ Bailey does indicate that one of the conductive elements could be “supported in a raised (or shielded) position” (page 5, line 10), but does not provide any description as to how that “raised position” would be obtained. Given the complete lack of any such description, and the other and repeated references to the “**thin** insulating layer,” it is more likely that Bailey would have used a separate shimming element to raise the conductive element. More importantly, this brief reference to “raised position” does not in any way teach or suggest the extruded flexible base being used here.

⁵ “4th Submission of Prior Art Under 35 U.S.C. 301” filed February 21, 2007 by attorney for Bird B Gone, Robert D. Fish (hereinafter, “4th Fish Submission”),

aspect of Bailey as showing a “Flexible base.”). For ease of reference, that portion of the 4th Fish Submission is reproduced here:

S No.	Patent Number	Braided element with three or more strands	Braided element attached to base by sewing	Flexible base	Application: Animal / Bird deterrent
7.	<u>WO1984004022A1</u>	Claims 2 and 4, Page 5 lines 12 - 17	Claim 4, Page 5 lines 12 - 17		Claim 1 and Page 1 lines 1-5

As this clearly shows, even the attorney for the copier Bird B Gone does not contend that Bailey teaches or suggests a flexible base, let alone one that is extruded. The attorney for Bird B Gone also submitted a “5th Submission of Prior Art Under 35 U.S.C. 301” on April 3, 2007 (“5th Fish Submission”), which was responsive to Applicant’s Reply to the 4th Fish Submission. The 5th Fish Submission similarly did not contend that Bailey disclosed a “Flexible base.” Nor does the 6th Fish Submission, submitted on May 14, 2007. Accordingly, it is beyond dispute that Bailey does not, such that Bailey does not anticipate, teach or suggest the pending claims.

At bottom, the claims on appeal call for an elongate extruded flexible base which is more than sufficient to distinguish Bailey, and to render the claims patentable.

However, there is more.

Also very significantly, neither of the 4th, 5th nor 6th Fish Submissions contend that Bailey shows the “flex aspect” of this invention in which individual strands within the attached braided elements move relative to one another as the base is flexed. Nor could the Fish Submissions have so contended, because Bailey plainly does not disclose that aspect of this invention. That the Fish Submissions do not contend otherwise is simply clear confirmation of that fact. Accordingly, this is yet another important distinction between what is shown in Bailey and the claimed invention here, and shows why this invention is patentable over Bailey (and the other prior art of record).

Similarly, although Bailey does mention that the conductive element can be “sewn,” there is no teaching whatsoever in Bailey as to any aspect of that sewing, or as to any resultant interaction between the manner of sewing and the ability of the individual strands of the sewn braided element to expand or contract after being sewn.

Regarding sewing, Bailey includes, in total, exactly two mentions of the word “sewn” and absolutely nothing else on the subject. Therefore, Bailey’s teachings in that regard are nothing more than a recognition, as we have seen in the other prior art of record, that sewing can be used to attach wire to a substrate material. Like all the other prior art of record, however, Bailey says nothing at all about the intended interaction of the braid relative to the flexible extruded base after sewing and during flex. In the invention here, and as now even more clearly spelled out in the amended claims, the braids are attached by sewing in which the braids are very securely attached to the base, but in a fashion that after being sewn the width of the braids remain free to expand and contract as the individual strands within each said braided element can move as the base is flexed. There is nothing at all in Bailey that teaches or suggests this result. And, as noted above, **neither of the 4th, 5th nor 6th Fish Submissions assert otherwise.**

And there is a very good reason for this. First, as mentioned above, Bailey was not at all concerned about creating a device that could be used on curved surfaces. So Bailey didn’t need to be, and was not concerned about, creating either a flexible base or addressing the stress and strain that the conductive elements would have to withstand in a flexed position. This is made all the more clear in that Bailey also spells out “metallised plastics tape” as an alternative conductive element (page 5, lines 16-17). Of course, this type of metallic tape would not stand up to being twisted and subjected to stresses and strains in flex.

Second, even though Bailey uses the term “braid” for the conductive element, he specifies it is “of the type known as “Monel” mesh sewn to the insulating layer” (page 5, lines 15-17). The metal mesh to which Bailey refers typically has perpendicularly juxtaposed warp and weft strands that are rigidly attached to one another with a specific alignment (as in screens of a particular “mesh” size), so there is no possibility of any movement of the individual strands as is called for in this invention. Independent claims-on-appeal 1 and 16 now exclude such a mesh, providing yet another reason why the claims are allowable over Bailey.

Therefore, Bailey does not teach or suggest this inventive concept regarding the sewing and the interaction of the individual strands of the sewn braid. Only through hindsight could one skilled in the art obviously start with Bailey and end up the claimed invention. Hindsight evaluation of obviousness of course remains inappropriate. *KSR Int’l v. Teleflex, Inc.*, 550 U.S. ___, 2007 U.S. LEXIS 4745, at *42 (April 30, 2007).

B. Objective Indicia of Non-Obviousness

As the Supreme Court has stated, objective indicia of non-obviousness must be taken into consideration when evidence of them is in the record. *Graham v. John Deere Co.*, 383 U.S. 1, 17-18 (1966); *KSR Int’l, supra*, 2007 U.S. LEXIS 4745 at *17-18. *See also, Alza Corp. v. Mylan*, 464 F.3d 1286, 1289-90 (Fed.Cir. 2006)(in addition to taking the objective indicia into consideration, there must be some “reasonable expectation of success” in a Section 103 evaluation that is not reliant on “hindsight” in light of the current applicant’s teaching”). Here, evidence of unsuccessful efforts and copying by others is not only in the record, it stands admitted *sub silencio* by Bird B Gone’s attorney.⁶

⁶ See the 5th Fish Submission filed in response to Applicant’s Reply to the 4th Fish Submission. In Applicant’s Reply, it is stated that “Bird B Gone . . . has slavish copied the invention disclosed in

Bird B Gone's flexible electric deterrent product (that is, before it saw and copied the invention here) was not the device shown in Bailey, or even anything remotely close to it. Rather, Bird B Gone's prior product offering in the flexible electric deterrent device category was its "Shock Track" device, shown here in a picture copied from the Bird B Gone website:

That device is also the subject of USPN No. 6,283,064, Figure 3 of which is depicted here:

this application (as shown in prior submissions by Applicant).” Although the 5th Fish Submission took issue with other statements made by Applicant in the Reply, the 5th and 6th Fish Submissions do not dispute the statement regarding slavish copying of the invention by Bird B Gone, whom attorney Fish represents.

This device uses metal strips 14 that are attached to a plastic base 4. The base has a number of gaps 6 and thus is articulated so as to allow it to be bent for attachment to non-flat surfaces. The wires 14 are “crimped in undulating fashion along their length, to provide them with give so that they will not disassociate from the base when it is bent or when the wires and base expand or contract at a different rate.” (‘064 patent, claim 1). And this device attaches the wires to the base “by a plurality of jaw like clips formed integrally with the strip along its upper surface, the clips positioned to grip and secure the wires at low points on the undulations of the wires.” (*Id.*, claim 3).

Once Bird B Gone saw the product of the instant invention, however, here is the product it introduced (shown in a photograph copied from the Bird B Gone website):

**Available in Grey, Black,
Stone & Terra Cotta!**

As can be seen, the Bird B Gone device includes two braided elements that are attached by sewing to spaced apart pedestal areas on the flexible, extruded plastic base, separated by a non-conductive portion. The braided elements are sewn in such a way that when the base is flexed, the

individual interwoven strands of the Bird B Gone product move, expanding or contracting laterally in order to partially absorb the flex stress. It is a direct copy of the invention claimed here, as shown in this Figure from the pending application:⁷

Imitation is not only the truest form of flattery, here it is also strong objective indicia of non-obviousness of the claimed invention.

Another prior art attempt to design a device that could be attached to both flat and curved surfaces is that developed by a company Ecopic and shown in USPNo. 6,006,698, depicted here:

⁷ The only differences are insignificant modifications in the cross-sectional shape of the base. Otherwise, it directly copies the inventive elements as claimed.

As seen here, the Ecopic device has solid metal strips **2** and **3** as the conductive elements housed within C-channels formed in the flat base **4**. Because the electric conductive strips are housed within the base as opposed to being on an upwardly exposed pedestal area, however, the Ecopic device had to go to the trouble of creating bent tabs **5** all along the length of each strip so that the bird (or other pest) may actually come into contact with both strips at the same time to receive the electric shock.

Because the strips **2** and **3** are solid, when the base/strip combination in the Ecopic device is bent, there is no “give” in the strip, so it slips within the channel (for example, if the base is curved convexly, the strips will pull inwardly, away from the ends of the base, making attachment of adjacent ends more difficult).

These features limit its effectiveness.

Thus, the Ecopic product and two Bird B Gone products discussed here graphically depict need, efforts, and then copying by others, all of which provided incredibly strong objective indicia of non-obviousness. Again, the Supreme Court’s decision in *KSR* reconfirmed the importance of these objective indicia in any obviousness evaluation.

No combination of the prior art shows or suggests a pest deterrent device having sewn-to-an-extruded-base braided elements and the flex aspect of the type disclosed and claimed here. Nor is there any reasonable expectation that Bailey alone or in combination with any other prior art of record would lead to the successful result for a truly flexible electric deterrent device as is shown and claimed in this application.

Accordingly, for the foregoing reasons, the claims on appeal should be allowed.

Respectfully submitted,

JONES DAY

Dated: July 13, 2007

VIII. CLAIMS APPENDIX

The following claims, as amended during prosecution, are on appeal.

Claim 1. An electric deterrent device for attachment to a surface comprising:

- a) an elongate base constructed of an extruded, flexible, non-conductive plastic material, said base having a cross-sectional configuration that includes a first side that will at least in part lie against the surface, and a second side, opposite said first side, said second side having at least two spaced apart areas that are separated by a non-conductive area;
- b) said base being attachable to either a flat or curved surface;
- c) at least a pair of electricity conducting elements attached to said spaced apart areas of said base, each said element comprising three or more strands interwoven to form a braided element rather than a mesh comprised of perpendicularly arranged warp and weft strands rigidly attached to one another at the warp/weft intersections, wherein when said base is bent in convex or concave flex the compression or extension stress placed on said braided elements is at least partially absorbed by individual strands expanding apart from, or contracting towards, other strands;
- d) said braided elements being attachable respectively to the positive and negative terminals of a power source; and
- e) said braided elements attached to said spaced apart areas on said base by sewing in which both of the braided elements are securely attached to said base, but allow a substantial number of the individual strands within each said braided element to move as the base is flexed.

Claim 2. The invention of claim 1 wherein said strands of said elements are substantially round.

Claim 3. The invention of claim 1 wherein said strands of said elements are substantially flat.

Claim 5. The invention of claim 1 wherein said braided elements have a substantially flat cross sectional configuration.

Claim 9. The invention of claim 1 wherein a plurality of said strands are stainless steel.

Claim 10. The invention of claim 1 wherein a plurality of said strands are copper.

Claim 11. The invention of claim 1 wherein a plurality of said strands are zinc coated copper.

Claim 12. The invention of claim 1 wherein said base is constructed of cellular, rigid or flexible polyvinyl chloride.

Claim 13. The invention of claim 1 wherein said base is constructed of any elastomeric material.

Claim 14. The invention of claim 1 wherein each said braided element resides within an appropriately sized channel in said base.

Claim 15. The invention of claim 1 in which said braided element comprises some strands of a conductive material and other strands of a non-conductive material.

Claim 16. In an electrical animal, pest or bird deterrent device comprising a base that is attachable to the surface from which the animal, pest or bird is to be deterred, and at least a pair of electrically conductive elements attached to the base and attachable to a power source, the improvement comprising said conductive elements comprising at least three individual strands woven together in a braid-like fashion rather than a mesh comprised of warp and weft strands in perpendicular arrangement rigidly attached at their warp/weft intersections, wherein when said base is bent in any direction, the stress placed on said conductive elements is at least partially absorbed by the width of said braid-like elements expanding or contracting as said individual strands move relative to one another, wherein said elements are attached to spaced apart pedestal areas on said base by sewing, said base substantially comprised of an extruded plastic material.

Claim 18. The invention of claim 16 in which some of said individual strands are made of a conductive material and some are not.

Claim 19. The invention of claim 16 in which said strands are made of metal.

Claim 20. The invention of claim 19 in which said strands are constructed of stainless steel, copper, or zinc plated copper, or a combination thereof.

Claim 21. The invention of claim 16 in which said base is constructed entirely of a non-conductive material.

Claim 23. The invention of claim 16 in which said base is constructed entirely of a material selected from the group of neoprene, fluoroelastomer, silicone, natural rubber, buna n (nitrile), buna s (SBR), thermoplastic rubber, synthetic polyisoprene, EPDM and polyurethane.

Claim 26. The invention of claim 16 in which said strands are woven tightly together.

Claim 27. The invention of claim 16 in which said strands are woven loosely together.

Claim 28. The invention of claim 1 in which one or more of said strands comprises a single wire.

Claim 29. The invention of claim 1 in which one or more of said strands comprises multiple wires, and at least one of said wires in at least one of said strands is of an electrically conductive material.

Claim 30. The invention of claim 16 in which one or more of said strands comprises a single wire.

Claim 31. The invention of claim 16 in which one or more of said strands comprises multiple wires, and at least one of said wires in at least one of said strands is of an electrically conductive material.

Claim 32. The invention of claim 1 in which said non-conductive area between said spaced apart areas comprises an extruded portion of said base.

Claim 33. The invention of claim 32 in which said non-conductive area between said spaced apart areas includes a channel formed in said base.

Claim 34. The invention of claim 16 in which said spaced apart pedestal areas are separated by an extruded portion of said base.

Claim 35. The invention of claim 34 in which said non-conductive area between said spaced apart areas includes a channel formed in said base.

"BIRD DETERRENT"

The present invention relates to bird deterrent means. In particular, the invention is directed to a device for deterring birds from perching or roosting on moored boats, the coping and cornices of buildings, railings and the like.

BACKGROUND ART

Owners of moored boats have long recognised, and suffered, the problem of birds perching on the boats. Not only do the birds leave feathers and excrement behind, but they also pose a health risk since they can introduce lice on to the boat. Many measures have been taken to deter birds from perching on boats. Such measures include wooden cut-outs painted as fierce blackhawks hung from shrouds, brightly coloured webbing and netting hung over the boat, brightly coloured streamers strung along the boat, tape recordings of the cry of the feared kittyhawk, and even a dead seagull hung upside down from the boom. While such measures may be of some effect initially, their deterrent value diminishes after a relatively short time as the birds become accustomed to the devices employed. For example, seagulls have been observed sheltering from the wind behind cut-outs of blackhawks, and perched on lines of streamers. Furthermore, such deterrents are either costly or of inconvenience to the boat owner.

In developing a solution to this problem the perching habits of birds have been studied. It has been observed that in the case of some species a preference is shown for perching upon a railing, while in other instances, especially in the case of seagulls which are perhaps the most troublesome birds to boat owners, the bird will alight upon the deck, roof, or other flat surface and immediately walk to the gunwale for a view of the water. A solution to the problem has taken into account these perching characteristics.

It is an object of the present invention to provide a means for alleviating the problem to boat owners and others caused by the undisturbed perching, or roosting, of birds.

WO 84/04022

PCT/AU84/00067

- 2 -

DISCLOSURE OF INVENTION

According to the present invention, there is disclosed a device for deterring birds from perching, or roosting, on a moored boat, a building or other structure having a broad surface attracting birds for perching, said device
5 comprising electrical circuit means for generating a pulsed electrical voltage at an output, and electrical conduction means supported upon said surface and connected to said output to form electrically charged regions, said regions
10 being arranged in lines in a spread-out pattern with said lines so widely spaced and located to permit movement of a bird between said lines but requiring to be crossed by the bird in its passage to an edge of the surface.

Preferably, the conduction means are flat metal
15 ribbons which are laid in parallel pairs closely-spaced along the surface of the boat, or structure, so that when a bird's foot bridges the conductors, it will receive an electric shock from the voltage pulses. In the case of a boat such an arrangement is adequate if the craft is
20 composed of timber, or fibre glass.

Alternatively, in the case of a metal hull, a single conductor can be laid over the boat insulated therefrom by a thin ribbon insulator, the other terminal of the output of the electrical circuit means being connected to the boat
25 body. Thus, when a bird provides an electrical path between the conductor and the boat body, it will receive an electric shock.

Typically, the electrical circuit means provides a high voltage/low current pulse output which shocks the bird,
30 but does not harm it. The shock is a sufficient deterrent to frighten the bird from the boat and, unlike other known deterrents, birds do not become accustomed to such electrical shocks.

If it be found that birds are perching only on a particular portion of the boat, e.g. the metal bow railing, a conductor insulated from the rail need only be arranged on the upper portion of the rail and the other terminal of the output of the electrical circuit means connected directly to the rail.

WO 84/04022

PCT/AU84/00067

- 3 -

It will be seen that the present invention utilizes the principle of electric fences which are used to restrict cattle within a certain area. However, such known electric fences cannot be applied directly to boats, or the other structures referred to above since the voltages used are not suitable and the arrangement of the conductors and their insulation from fence posts are inapplicable to boats. In the case of an electrical fence the earth is one terminal of the applied power.

The pattern of the electrical charged regions is broad, i.e. quite widely spaced in the order of at least 300 mm. Narrow spacing might at first be considered necessary to ensure that an alighting bird does not avoid contact with the regions. Such close spacing of the electrical conductors would detract from the appearance of a boat as well as add considerably to the cost. However, as mentioned previously the perching habit of many of the troublesome birds which entail early movement of the bird towards the gunwale enables the pattern of the lines of conductors to be widely spread and therefore intercept the movement of the bird shortly after alighting.

In the present invention, the conduction means is preferably constructed as flat ribbon which can be adhered to the horizontal surfaces of the hull and cabin of the boat but is insulated from the surface by a thin insulating layer provided with a pressure-sensitive adhesive. Electrical conductor strips are exposed on the topside of the ribbon for contact with the bird. In this manner, the conductors need only be laid on those portions from which the birds are to be deterred, and the high voltage pulses do not interfere with other electronic equipment on board the boat. The same ribbon may be used on the topside of rigging.

Where it is intended to deter birds from perching on metal railing, the ribbon applied on the topside of the metal rail requires only a single electrical conductor with the opposite terminal of the electrical circuit means connected directly to the metal rail.

BRIEF DESCRIPTION OF DRAWINGS

Notwithstanding any other form of the invention, a

WO 84/04022

PCT/AU84/00067

- 4 -

preferred embodiment thereof will now be described with reference to drawings in which:

Fig. 1 is a partial diagrammatic representation of a marine launch to which the bird deterrent device according to the invention has been applied;

Fig. 2 is a perspective of an electrical control for said device; and,

Fig. 3 is a circuit diagram of the electrical voltage pulser.

BEST MODE OF CARRYING OUT THE INVENTION

As shown in Figs. 2 and 3, the control 10 for the bird deterrent device includes an electrical circuit (Fig. 3) in a housing 11 which can be affixed in the cockpit 12 of the boat 13 (Fig. 1). The input of the control 10 is connected to a D.C. voltage supply, typically a 12 volt battery, by leads 14. A pulsed output voltage is provided at the output terminals 15 of the control 10. The amplitude of the voltage pulses can be controlled by switch 16 and the frequency of the pulses can be varied by a control 17. A light emitting diode 18 can also be provided to indicate the impulse timing.

A pair of conductors 19 and 20 are connected to respective output terminals 15 of the control 10. The conductors 19 and 20 are flat metal ribbon conductors with an adhesive coating on their underside so that they can be affixed to a broad surface of the boat such as the deck 21 from which the birds are to be deterred from perching. Preferably, the conductors 19 and 20 are spaced about 15 mm apart and also include a thin underside electrically insulating layer which insulates the live conductor from the boat deck 21. The pair of conductors 19,20 are laid parallel and closely spaced so that a bird's foot can span both conductors 19,20. A bird thereby provides a conductive path between the conductors 19,20 and will receive an electric shock from the next voltage pulse produced by the control 10. Both conductors 19 and 20 may be carried upon a common insulating layer.

Alternatively, the ribbon may carry a single electrical conductor, say conductor 19, upon the insulating

WO 84/04022

PCT/AU84/00067

- 5 -

layer with the output terminals 15 connected respectively to the conductor 19 and the metal railing 22 of the boat, or to the deck 21 if composed of metal. Although in most instances the ribbon of conductors 19 and 20, or conductor 19 alone, will be permanently attached to the deck 21, it may be instead affixed upon a plastics sheeting which can be laid out and recovered as desired. Also whether conductors 19 and 20 are supported directly upon the deck 21 or the plastics sheeting, at least one of the conductors 19, 20 may be supported in a raised (or shielded) position to minimise any shorting effect which might be created by the presence of dew or rain. Furthermore, connection from the output terminals 15 of the control 10 to the conductors 19 and 20 is via clamps or even a stud fastener (not shown), while each conductor 19 and 20 may be a flexible metal braid, of the type known as "Monel" mesh sewn to the insulating layer, or may be a metallised plastics tape.

The electrical circuit for the control 10 is shown in Fig. 3. The circuit is powered from a voltage supply which may be from 9V to 28V DC. A voltage regulator LM 317T is connected to the voltage supply so as to provide a steady voltage power supply to the circuit. Diode D1 is used as a protection diode and capacitor C1 as a filter capacitor. Resistors R5 and R6 adjust the output voltage of the regulator to approximately 8V.

Oscillations produced in the windings W1 and W2 of transformer T1, using ancillary network Q2, resistors R7 and R8 and capacitors C2 and C4 cause approximately 120 volts to appear across the winding W3. This voltage is fed to a half-way rectifier D2 which in turn charges a 0.47 uf metallized polyester capacitor C5 which is connected in series with the primary winding W1 of coil T2 which has approximately 200 turns. This charge of the capacitor produces approximately 2KV in the secondary winding W2 which has approximately 5000 turns.

A 2N 6027 programable unijunction transistor (PUT) Q1 initiates a discharge cycle by supplying a brief pulse to the gate G of the SCR. This causes the SCR to turn on, discharging the capacitor C5 through the coil W1. The SCR

WO 84/04022

PCT/AU84/00067

- 6 -

will remain on until the discharge current falls below its "hold on" current. The rate at which the PUT transistor supplies trigger pulses to the SCR depends on two factors, viz. a reference voltage set on its own gate by the ratio of resistors R2 and R3, and the time constant of resistor R4 and capacitor C3. When capacitor C3, and hence the anode A of transistor Q1, reach a voltage of 0.6V higher than the reference voltage, the device switches on. This allows the capacitor 3C to discharge into the gate G of the SCR thereby supplying a trigger pulse. The neon fires at approximately 90V through resistor R10 and is used as an indicator. The pulse produced with a 50 ohm load, approximately once every second, will have a voltage of 2KV at 250mA.

The circuit imposes only a small drain on the voltage supply, typically 25mA into a 500 ohm load at 2KV. Accordingly, battery life will not be a problem. Furthermore, when a high voltage shock is imparted to a bird, only a negligible amount of current, and hence power is used. The device can be activated merely by a flick of a switch and will not interfere with normal sailing or motoring activities.

The foregoing describes only one embodiment of the present invention and modifications which are obvious to those skilled in the art may be made thereto without departing from the scope of the invention.

CLAIMS

1. A device for deterring birds from perching, or roosting, on a moored boat, a building or other structure having a broad surface attracting birds for perching, said device comprising electrical circuit means for generating a pulsed electrical voltage at an output, and electrical conduction means supported upon said surface and connected to said output to form electrically charged regions, said regions being arranged in lines in a spread-out pattern with said lines so widely spaced and located to permit movement of a bird between said lines but requiring to be crossed by the bird in its passage to an edge of the surface.

2. A device according to claim 1, wherein said electrical conduction means comprises a pair of electrical conduction leads fixedly mounted upon an electrically insulating layer located upon said surface.

3. A device according to claim 2, wherein said insulating layer is a strip coated on its underside with a pressure-sensitive adhesive for fixing to said surface

4. A device according to claim 2 or 3, wherein said pair of conduction leads are parallel lengths of flexible metal braid sewn onto said insulating layer.

5. A device according to claim 2 or 3, wherein said pair of conduction leads are parallel strips of metallized plastics tape.

6. A device according to any one of the preceding claims, wherein said spacing between adjacent lines of said electrically charged regions is at least 300 mm.

7. A device according to any one of the preceding claims, wherein to provide bird deterrents on rigging and railings of said boat said electrical conduction means is applied on the topside thereof.

8. A device according to any one of the preceding claims, wherein said electrical circuit means comprises a step-up transformer including a transistorised ancillary network associated with its primary winding whereby applied low voltage induces a voltage above 1KV in its secondary winding, and a storage capacitor receiving a charge from said secondary winding and being discharged to said output

WO 84/04022

PCT/AU84/00067

- 8 -

by firing of an SCR.

9. . . A device according to claim 8, wherein firing of said SCR is controlled by a timing circuit including a unijunction transistor.

10. A device for deterring birds substantially as hereinbefore described with reference to the accompanying drawings.
